(57) **ABSTRACT**

An enclosure for a surveillance camera includes a housing having front, rear, top, bottom and opposing side walls. A camera dome projects downwardly below the bottom wall. A support structure includes a vertical channel attachable to a vertical post for supporting the housing on a post. A cover is selectively attachable to both the top and bottom walls, the cover normally being attached to the bottom wall to cover and protect the camera dome during transport or when surveillance is not required and attached to said top wall to expose said camera dome when in use during surveillance. The top and bottom walls are provided with connecting members for easily removing or securing the cover by flipping it 180° when moving the cover between the top and bottom walls of the housing when mounted on the support structure and post.

# **CONVERTIBLE MOBILE SURVEILLANCE CAMERA ENCLOSURE FOR SELECTIVELY PROTECTING CAMERA DOME**

## **BACKGROUND OF THE INVENTION**

### **1. Field of the Invention**

The present invention generally relates to surveillance systems and, more specifically, relates to mobile surveillance camera convertible enclosure for protecting camera dome during transportation.

### **2. Description of the Prior Art**

Surveillance cameras are widely used for security and monitoring purposes. In some circumstances, the surveillance cameras are enclosed within housing such as disclosed in U.S. Pat. Nos. 6,735,382; 6,354,749 and 5,852,754. These housings generally shelter the surveillance camera from the elements, protect the camera from vandalism, conceal the camera from view to prevent distracting from the aesthetic quality of an area, and the like.

While existing monitoring systems have traditionally been adequate for their intended purposes, they have not been satisfactory in all respects. For example, many cameras are mounted by fixing them to a light post or utility pole in a manner that does not always allow easy and simple removal while securing the camera housings or enclosures. Also, because these cameras tend to be costly, municipalities have not always been able to place these cameras at all locations of interest. Likewise, promoters of events, such as street fairs, parades, etc. frequently desire to provide such surveillance cameras short term to protect the safety of the public attending such events. However, the locations where such events take place are not always equipped with surveillance cameras. Leasing such units even for temporary use requires transport to and from the location and handling at the locations requiring easy and quick installation of units without damaging the equipment and, in particular, the delicate camera dome that typically projects beyond the walls of the camera enclosure. Use of packing materials has not proved satisfactory since these can still make contact with the outside surface of the dome and, therefore, scrape and scratch it. Also, this is not a "green" solution since such packing materials, such as foam bubbles, molded foam blocks, paper, etc. are frequently discarded after use. Thus, the existing enclosure and mounting structures have not promoted mobility, ease of use and neither secure mounting nor promoting the movement of rented or leased units for temporary use at different locations such as special events or enhancing security in trouble areas.

Published patent application 2009/0096918 is for a protected security monitoring box. However, the lens of the camera stays exposed outside the housing. The camera is mounted so that its angle of inclination can be adjusted to accommodate the needs of the space that is being monitored.

In Published patent application 2008/0100707 a temporary surveillance system is disclosed. While this reference primarily discloses the use of conventional cameras with a dome mounted on a post there is no discussion about protecting this dome during transport or use.

A camera enclosure is disclosed in U.S. Pat. No. 8,137,009. The patent is primarily concerned with blocking or disabling the camera to protect the privacy of individuals in the area. However, this can be overridden in the case of emergencies or special situations at which times the blocking members or elements can be moved to expose the camera and enable it. This can be done by remote control. The case or housing is not

2

used to protect the dome during transport as the unit appears to be permanently affixed to a horizontal surface such as a ceiling.

Reissue Pat. 837709 is for a system for recording and modifying behavior of passenger in passenger vehicles. The system includes housing for a camera the lens of which is always enclosed within the housing. A hinged cover can be opened to access the camera since the camera is always within the housing the camera is not at least partially mounted within a hemispherical dome that is positioned outside of the housing.

U.S. Pat. No. 4,160,999 is for a mounting arrangement for a television monitoring camera. However, this camera, as well, is permanently mounted in what appears to be a suspended ceiling. The cover does move between open and closed hinged positions but this is to provide access to the interior of the enclosure for purposes of maintenance. This arrangement is not designed for transporting a portable surveillance system that utilizes a dome or spherical lens that protrudes beyond a housing or enclosure.

U.S. Pat. No. 3,993,866 is for a camera capsule. This patent discusses the camera housing and how it can be packaged and shipped in a way that causes a base portion to protect the dome during storage and shipment. However, this involves inserting the dome in an inverted position with respect to the base so that the dome projects into the base portion. It is only after the dome is placed in this position that the dome remains untouched during shipment. This protects the chromium applied to the concave surface of the dome and so that the dome does not become scratched or otherwise distorted or damaged. However, requiring the dome to be manually gripped and inverted or flipped is not a practical solution since inevitably the coating can be contacted and the dome can be scratched or otherwise damaged when it is transitioned from one position to another. It also opens the possibility for the dome to be inadvertently dropped when it is detached from the case and handled in an attempt to reverse its orientation.

## **SUMMARY OF THE INVENTION**

Accordingly, it is an object of the present invention to provide a mobile surveillance camera convertible enclosure that overcomes the disadvantages that are inherent in presently known surveillance camera enclosures.

It is another object of the invention to provide a camera enclosure that is suitable for transportation from one location to another for temporary surveillance use at given locations, such as for events, periodic monitoring, etc.

It is still another object of the invention to provide a mobile surveillance camera enclosure that protects the projecting dome or lens of a camera within the enclosure during transport and during storage.

It is yet another object of the invention to provide a mobile surveillance camera enclosure as in the previous objects that is simple in construction and economical to manufacture.

It is a further object of the invention to provide a mobile surveillance camera enclosure of the type under discussion that obviates the need to consume and discard packing materials, such as foam panels, foam bubbles, bubble wrap, etc. for covering and protecting the dome of a camera enclosure during storage and transport.

It is still a further object of the invention to provide a mobile surveillance camera enclosure as suggested in the previous objects that is simple and convenient to use and can be quickly mounted and de-mounted at a site to be monitored and requires no tools to do so.

3

In order to achieve the above and other objects, it will become evident hereinafter, a mobile surveillance camera enclosure for protecting a camera dome during transport includes a main case of the enclosure for housing the surveillance camera with its associated electronics components. The case has a removable cover normally attached to the lower end of the case to cover and protect the dome without contacting the dome which, in turn, protects the video camera during storage and transport. A support structure is mountable on a pole at a location where surveillance is to take place and includes straps for accommodating poles of different sizes the securing the support structure to the pole. The support structure includes a first surface suitable for abutment against a surface of said enclosure and a second surface suitable for abutment against the pole. Detachable connecting members are provided for selectively securing the case to the support structure. Once the case is securely mounted on a pole, a lower removable protective cover initially mounted on the bottom of the case can be removed by means of suitable fasteners, such as separable hinges, and flipped 180° and securely mounted and attached using similar fasteners at the top of the enclosure where it is retained until the camera enclosure is to be removed from the pole at which time the cover is replaced on the bottom of the case to cover and protect the camera dome to ready the unit for transport.

#### BRIEF DESCRIPTION OF THE DRAWINGS

Those skilled in the art will appreciate the improvements and advantages that derive from the present invention upon reading the following detailed description, claims, and drawings, in which:

FIG. 1 is a front elevational view of the mobile surveillance camera convertible enclosure in accordance with a first embodiment of the present invention, shown with a support structure in the background on which it is can be mounted;

FIG. 2 is a rear perspective view of the enclosure shown in FIG. 1, showing details of the support structure connectable to a pole during use and the support brackets or flanges on the enclosure for securing same to the support structure;

FIG. 3 is similar to FIG. 2, and shows the manner in which the support structure and the enclosure mounted thereon are attached to a pole prior to removal of the lower cover and exposure of the mobile surveillance camera dome;

FIG. 4 is a rear perspective view of details of the support structure and the manner in which the support structure is attached to the pole;

FIG. 5 is similar to FIG. 4 showing a perspective view from the opposite side and illustrating additional details of the connectors for securing the case to the support structure;

FIG. 6 is an enlarged fragmented view of the construction shown in FIGS. 1-5 and illustrates the separable hinges that allow the removal of the protective cover to be removed from the top of the case and attached to the bottom, and vice versa;

FIG. 7 is a perspective view showing additional details of the separable hinges shown in FIG. 6;

FIGS. 8 and 9 show the manner in which the removable cover is secured to the top of the camera enclosure by means of the separable hinges and/or removed therefrom after use for reattachment to the bottom of the enclosure;

FIG. 10 is a perspective view showing the removable cover secured to the top of the camera enclosure and the initially protected dome exposed at the bottom of the enclosure to allow surveillance with the internal camera;

FIGS. 11 and 12 are front and rear perspective views of the arrangement shown in FIG. 10;

4

FIG. 13 is a front perspective view of a second embodiment in accordance with the invention;

FIG. 14 is a rear perspective view of the embodiment shown in FIG. 13;

FIG. 15 is a side elevational view of the embodiment shown in FIGS. 13 and 14;

FIG. 16 is a perspective view of the embodiments shown in FIGS. 13-15, showing the camera dome cover removed from the main enclosure or cabinet and showing some details of the shoulder bolts and associated slots in the cover for engagement with the bolts;

FIG. 17 is a top perspective view of the cabinet or housing shown in FIGS. 13-16 showing the locations and details of the shoulder bolts receivable within associated slots in the protective cover;

FIG. 18 is similar to FIG. 14 shown with the cover removed from the lower part of the cabinet and placed on the upper part of the cabinet to expose the camera dome; and

FIGS. 19 and 20 are rear elevational view of the cabinet of the second embodiment illustrating the self aligning feature of the cabinet with the post and the laterally spaced wing members that engage the support channel attachable to a post; and

FIG. 20 is a rear perspective view of the cabinet and post support channel without the posts.

#### DESCRIPTION OF PREFERRED EMBODIMENTS

Referring now specifically to the Figures, in which identical or similar parts are designated by the same reference numerals throughout, and first referring to FIG. 1 a first embodiment of a mobile surveillance camera convertible enclosure for protecting a camera dome during transport is generally designated by the reference numeral 10.

The enclosure 10 includes a main case or housing 12 having a bottom or proximate end 12a and a top or remote end 12b and a front door or panel 12c for accessing the internal compartment of the case that houses the surveillance camera and associated electronic components. A front access door handle 14 can be used to open and close the front door or panel 12c to provide access to the case.

A carrying handle 16 is provided for carrying the case or housing during transport from a storage location to a location to be watched or between any such locations.

An important feature of the present invention is the provision of a removable cover 18, shown secured to the bottom or proximate end 12a of the case. The cover 18 is normally secured to the case as shown during storage and/or transport of the enclosure from one location to another. The cover 18 is preferably provided with rubber feet 20 for protecting the cover 18 when the enclosure is placed on the ground or other surface.

Also referring to FIG. 2, a support structure generally designated by the reference numeral 22 is used to support the enclosure 10 on a pole or the like during use. The support structure 22 includes an upright U-shaped channel 22a provided with spaced opposing pairs openings or slots 22b. An upper arm 22c and a spaced lower arm 22d are secured to the upright channel 22a. The arms 22c and 22d have a generally U- or C-Shaped configuration to provide inwardly directed connecting portions 22e. The connecting portions 22e on each arm 22c and 22d are spaced from each other distances generally corresponding to the width of the enclosure, housing or case 12 to substantially abut against the sides of the case with some small clearance to allow easy and quick positioning of the case between the connecting portions and abutment

5

against the channel **22a** as will be described while preventing excessive lateral movements. L-Shaped brackets or flanges **24** provided on the sides of the case or housing **12** are positioned generally above the connecting portions **22e** when the case is to be mounted on a support structure **22**, each of the brackets **24** having a vertical portion **24a** fixedly secured to the side of the case or housing, such as by welding, and a horizontal portion **24b** that extends outwardly to be positioned generally directly above an associated connecting portions **22e**. The horizontal portions are provided with a hole for receiving of a ball-lock pin or other suitable fastener for quickly, easily and conveniently locking the case or housing **12** on the arms **22c**, **22d** and prevent inadvertent separation thereof when the case or housing is mounted on the support structure **22**. The lock pin **26** may be provided, for example, with a ring **26'** that can be readily gripped by a user and pulled upwardly to unlock the lock pin and allow the enclosure to be lifted and separated from the arms **22c**, **22d** when it is desired to move the unit. Referring to FIG. 4, there is shown a phantom outline, a lock member **28** that can cooperate with the lock pin **26** to retain the lock pin in place and allow separation only when the ring **26'** is pulled upwardly to retract the ball in the lock pin and allow the removal of the pin. Alternatively, if the arms **22c**, **22d** are U-channels, a hole in the upper surface can also receive the pin and serve a similar function. The fastening method described is a presently preferred method of securing the closure to the support structure. However, it will readily be evident to those skilled in the art that other fasteners, including linkage pins, draw bars, clips and other fasteners can be used, with different degrees of advantage. Any such fastener can be used that is convenient and easy use to quickly and easily attach or remove the housing to the support structure or securely fix it to that structure.

Referring to FIGS. 3-5, straps **32** are shown used to secure the support structure **22** to a pole **34**. Each strap is provided with a buckle **32a** and a free end **32b** that can be passed through the buckle for adjusting the strap and tightening it about a pole. The strap **32** may be made of a strong nylon material, although other materials can also be used, with different degree of advantage. Adjustable clamps may also be used made of metal or plastic. The enclosure mounting bracket that is illustrated in U.S. Pat. No. 6,185,303 that uses an adjustable strap that extends about a pole and a ratchet device for drawing the strap in and tightening it about the pole can also be used. The aforementioned patent is incorporated as it fully set forth herein for the disclosure of such enclosure mounting bracket. The specific method of attaching or securing the support structure to a pole is not critical for the purposes of the present invention.

As indicated, the important feature of the present invention is the removable cover **18** that can be readily and conveniently removed from the bottom or proximate end **12a** of the case and placed and attached to the remote or top end **22b** of the case **12**. Any suitable fasteners for allowing such quick disconnect or connect can be used. Referring to FIGS. 6-9, detachable hinges **36** are shown secured by screws and include fixed hinged portions **36a** secured to the main case or housing **12** and movable hinge portions **36b** secured to the cover **18**. As best shown in FIG. 7, the fixed hinge portions **36a** have channels **36c** and the removable portions **36b** have pins **36d** dimensioned to be readily received within the channels **36c**. By shifting the cover laterally as suggested in FIGS. 6-9, the hinges can be separated, the cover removed and detached from the case **12** and reattached to the opposing end using similar fixed hinge portions **36a**. Other detachable fasteners that may be used in lieu of the hinges shown. By way of example, turn lock fasteners, catches or latches, tick-tite clo-

6

sures, toggle clips, and ring and hook fasteners can be used with different degrees of advantage.

Referring to FIGS. 10-12, a dome **40** is shown at the bottom **12a** of the housing after the cover **18** has been removed from the bottom of the housing or case and flipped 180° and secured to the top of the case, showing the arrangement when the enclosure is used and the camera can survey the area through the dome **40**. When the enclosure is no longer used for that purpose it can be covered again as shown in FIG. 2, for example, whether or not the unit is to be transported to another location or simply protected from the elements or otherwise when surveillance is not desired.

It will be clear, therefore, that the cover **18** is normally a part of the enclosure. By simply separating it from one end and attaching it to the other end, the dome **40** can be protected when used without the need for other protective or packing materials to protect the dome against scratching, cracking, etc. that would deteriorate the performance of the camera. This way, the dome is always in perfect condition for use any time when it is mounted at a permanent or temporary location.

Referring now to FIGS. 13-19, a second embodiment of the invention is illustrated and designated by the reference numeral **10'**. The two embodiments share the features that they are both mountable on a pole and include a support structure that has a first surface suitable for abutment against a surface the enclosure or housing or cabinet and a second surface suitable for abutment against the pole, typically having circular or hexagonal cross sections. Connecting members are provided with both embodiments for selectively securing the case to the support structure. However, once so supported, they both have the ability to remove the lower protective cover initially mounted on the bottom of the case and flipped 180° and placed on and securely attached to the top of the enclosure, housing or cabinet where it is securely retained until the camera enclosure is to be removed from the pole at which time the cover is again replaced on the bottom of the case, housing or enclosure to cover and protect the camera dome to ready the unit for transport.

Referring to FIGS. 14, 15, 17-19 extending laterally to each side of the upright channel **22a** are opposing wing members **42** including lower portions **42a** and upper portions **42b**, the upper portions being inclined forwardly, as viewed in FIG. 14, and terminated with a upwardly-directed tab **42c**. While the specific configuration of the tab **42c** is not critical, as will become evident, in the embodiment shown the tab **42c** is generally rectangular and is oriented vertically when the channel **22a** is mounted on a vertical post. The lower portions **42a** and the tabs **42c** are, therefore, substantially parallel to each other but horizontally offset from each other so that the portions **42a** are within the dimensions of the side walls of the channel **22a** while the tabs **42c** are arranged forwardly of the channel.

Also referring to FIG. 20 the wing members **42** and the channel **22a** form part of a support member for the housing, enclosure or cabinet, as previously suggested. In the second embodiment, however, the upper wall of the housing, or cabinet enclosure is formed, at the rear thereof, with top wall extensions **44** spaced from each other to correspond to the positions of the wing members **42** on the channel **22a**. Each extension **44** includes a generally vertical portion **44a** that extends vertically downwardly at the rear of the cabinet or housing and is formed with an outward extension **44b** rearwardly in relation to the vertical portion **44a**. The portions **44a**, **44b** are provided with openings, windows or apertures **44c** dimensioned to receive the upwardly directed or extending tabs **42c**. The outwardly extending portions **44b** make contact with the inclined upper portion **42b** to slide thereon

7

when aligned and lowered relative thereto to draw the cabinet rearwardly towards the channel **22a** when the housing, cabinet or channel are aligned as shown and allowed to be lowered until the tabs **42c** are fully received within the openings or windows **44c**.

The height of the channel **22a** is preferably selected to normally extend above the upper wall **44** so that a user can visually align the cabinet and center it to facilitate placement of the channel **22a** between the two laterally spaced wing members **42**. As should be clear, once so aligned the cabinet or enclosure can be lowered to provide the engagement and support described. Once the cabinet or enclosure is fully lowered it centers itself in relation to the channel **22a** and, once fully seated, a hole **46** in the cover becomes aligned with a corresponding screw or other fastener **48**, such as a quarter-turn wingnut or any other locking screw to secure the cover against vertical upward movement relative to the case, cabinet, enclosure or housing **12**. This prevents the cover from being inadvertently or improperly lifted and removed or separated from the housing or cabinet.

In FIGS. **13-15** the cover **18** is shown in its protective position, at the lower end of the cabinet, enclosure or housing wherein the cover **18** protects the camera dome as discussed above. Referring to FIGS. **16** and **17**, the housing, enclosure or cabinet **10** is provided with a plurality of shoulder bolts at the respective upper and lower walls and associated key-shaped slots **48** on the cover **18**. The shoulder bolts **46** are dimensioned to be received through the enlarged ends of the key-shaped slots and then moved into the narrow ends of the slots to effectively engage or disengage the cover **18** from the housing. In FIGS. **16** and **17**, the cover **18** is shown moved slightly forwardly of the housing or cabinet as during the step of connecting or disengaging the cover from the cabinet. Once the cover is disengaged from the bottom shoulder bolts the cover can be moved to the top of the cabinet or housing, flipped **180°** and secured to the top of the cabinet by having the slots in the cover engage the upwardly extending shoulder bolts. Once the shoulder bolts have been received within the associated slots the cover **18** can be pushed rearwardly to effectively engage and connect these members to each other. This exposes the camera dome **40**, as discussed with the previous embodiments. As shown in FIGS. **14**, **15** and **19**, for example, any suitable fastener **50**, such as a locking screw, can be used to secure a lanyard or any other cord **52** at one end, the other end being secured to the back of the cover **18** by means of another similar fastener, such as a screw **54**, as shown in FIG. **14**. The lanyard **52** is selected to provide sufficient strength and tension to support the weight of the cover **18** if dropped. Typically, the cover **18** may weigh 5-10 lbs and the lanyard **52** is selected to withstand tension of 100 or more pounds to provide a good safety margin in the event that the cover is inadvertently dropped when moving the cover from the bottom of the housing to the top thereof, or vice versa. Since the enclosure may be mounted on a pole or post at a high elevation the lanyard is intended to prevent the cover from dropping and creating injury to a person below. The screw **50** can be connected to either of the side panels or walls of the housing, depending on the position of the door hinge and the direction that the door opens to minimize interference with the opening and closing of the front door **12b**.

While two embodiments have been shown that facilitate the attachment of the cabinet or housing to a vertical channel, other methods will become evident to those skilled in the art. In each case, the construction used needs to facilitate the mounting of the cabinet on the pole and subsequent move-

8

ment of the cover **18** between the top and the bottom of the cabinet, once so mounted, preferably by one person in the field.

While the invention was illustrated and described as mobile surveillance camera convertible enclosure for protecting camera dome during transportation, it is not intended to be limited to the detail shown, since it will be understood that various emotions, modifications, substitutions and changes in the forms and details of the formulations and constructions illustrated and its operation can be made by those skilled in the art without departing in any way from the spirit and scope of the present invention.

What is claimed:

1. An enclosure for a surveillance camera comprising a housing having front, rear, top, bottom and opposing side walls; a camera dome projecting downwardly below said bottom wall;

a support structure attachable to a vertical post for supporting said housing on a post;

a cover selectively attachable to both said top and bottom walls, said cover normally being attached to said bottom wall to cover and protect said camera dome during transport or when surveillance is not required and attached to said top wall to expose said camera dome when in use during surveillance, said top and bottom walls being provided with connecting means for readily removing or securing said cover by flipping said cover **180°** when moving said cover between said top and bottom of said housing when mounted on said support structure.

2. In the enclosure defined in claim 1, wherein said support structure includes an elongate channel and at least one transverse arm dimensioned to engage said housing.

3. In the enclosure defined in claim 2, wherein a pair of spaced arms are provided along said elongate channel.

4. In the enclosure defined in claim 2, wherein said elongate channel has a U-shaped cross-section open in a direction facing away from said housing when supporting said housing.

5. In the enclosure defined in claim 2, wherein said channel is provided with spaced apertures or slots along at least a portion of its elongate length to enable said elongate channel to be secured to the post by means of at least one strap or other elongate fastener.

6. In the enclosure defined in claim 2, wherein said at least one arm is provided with connecting portions positionable in close proximity to said opposing side walls, said housing being provided with brackets or flanges on said opposing side walls arranged to register with said connecting portions to support said housing by said at least one arm.

7. In the enclosure defined in claim 2, further comprising locking means for selectively locking and unlocking said housing from said at least one arm.

8. In the enclosure defined in claim 7, wherein said locking means comprises a lock pin.

9. In the enclosure defined in claim 1, wherein said connecting means comprises separable mating hinge portions, a first of said mating hinge portions being mounted on said cover and a second of said hinge portions being mounted at said top and bottom walls of said housing, said first of said mating hinge portions being mateable with either one of said second of said hinge portions, whereby said cover can be readily attached and detached from either one of said top or bottom walls.

10. In the enclosure defined in claim 1, further comprising an elongate cord secured at one end to said housing and secured at an opposing end to said cover, said cord having a length to allow free movement and attachment of said cover to

9

both said top and bottom walls of said housing while preventing damage to said cover if inadvertently released or dropped.

11. In the enclosure defined in claim 1, further comprising securing means on said top and bottom walls and said cover to selectively secure said cover to one of said top and bottom walls when placed directly over said top wall or below said bottom wall to thereby prevent said cover from being inadvertently or improperly lifted or removed or separated from said housing.

12. In the enclosure defined in claim 1, wherein said support structure includes an elongate channel and an upwardly inclined wing member secured to said elongate channel, a downwardly inclined wall extension on at least one of said top and rear walls arranged to engage an associated upwardly inclined wing member to facilitate registrations of said inclined wall extension and with an inclined wing member for supporting said housing thereon.

13. In the enclosure defined in claim 12, wherein opposing wing members are provided extending laterally to each side of said elongate channel and wall extensions are provided on said housing arranged to register with and be supported by said opposing wing members.

14. In the enclosure defined in claim 13, wherein said opposing wing members include upwardly extending tabs and said wall extensions include openings or windows dimensioned to receive associated tabs.

10

15. In the enclosure defined in claim 11, wherein said securing means comprises a hole in one said top and bottom walls and said cover and a fastener in the other of said top and bottom walls and said cover, said fastener being configured to be received within said hole to provide locking engagement.

16. In the enclosure defined in claim 15, wherein said fastener comprises a locking screw.

17. In the enclosure defined in claim 16, wherein said locking screw comprises a quarter turn wing nut.

18. In the enclosure defined in claim 16, wherein said locking screw comprises a shoulder bolt.

19. In the enclosure defined in claim 15, wherein said hole is a key-shaped slot in said cover and said fastener comprises a shoulder bolt on said top and bottom walls dimensioned to be received through enlarged ends of said key-shaped slot and movable into narrow ends of said slot to engage and retain said cover to said housing.

20. In the enclosure defined in claim 1, further comprising at least one of a carrying handle on said top wall for carrying said enclosure when said cover is secured to said bottom wall and rubber feet on said cover when said enclosure is secured to said bottom wall and rested on the ground or other support surface.
